13. ABSTRACT ( <i>Maximum 200 words</i> ) Animal models of decompression sickness (DCS) have been developed in various species. The Naval Medical Research Institute (NMRI) developed a porcine model of DCS through the course of more than 300 dives, encompassing widely diverse dive profiles on air and mixed-gas. Some of these profiles include decompression stops, some do not; some profiles include post-dive treatments, and others do not. This report provides the collected database of non-saturation porcine dives undertaken to develop the NMRI porcine DCS model. It correlates the dive profiles with summaries of the various observed outcome measures.

## **ACKNOWLEDGMENTS**

This research was supported by the Navy Medical Research and Development Command Work Unit 63713N M0099.01B-1610. The opinions expressed in this paper are those of the authors and do not reflect the official policy or position of the Department of the Navy, the Department of Defense, or the U.S. Government. No experiments involving animal subjects were conducted solely for the compilation of data represented here. Data were taken from animal experiments previously reviewed and approved by the Institutional Animal Care and Use Committee. This work was done by U.S. Government employees as part of their official duties; therefore, it cannot be copyrighted and may be copied without restriction.

We would like to thank Dr. Jonathan Broome who initiated the swine model work at NMRI. Much of the data presented here are the result of his efforts. We also want to recognize the consistent efforts of the dedicated laboratory personnel who contributed throughout the 3-year data accumulation period: Ms. Catherine Jones, Mr. Melvin Routh, and Petty Officers Harold Boyles and Norm Wilt. Finally, we thank Ms. Susan Mannix for editorial support and assistance.

## **INTRODUCTION**

The Naval Medical Research Institute (NMRI) developed a porcine model of decompression sickness (DCS) as a tool for the prospective study of factors that may influence the risk of DCS in an animal (1-3). The porcine model has been established as a successful animal model for research in several human pathologies (4-7). This model has also proved to be highly flexible and has been applied to multiple areas of investigation including practical, clinical, and basic science issues (8-11). These areas include the identification of physical, physiological, and environmental risk factors, the comparison and assessment of treatment strategies; and the research into histopathological, cellular, microvascular, and even genetic determinants of susceptibility to DCS (12-14). We recently adapted the porcine model to explore saturation profiles and evaluate therapeutic intervention stratagems.

The pooled data included here represent the current generation of the NMRI porcine model from its initiation in 1994 through the last non-saturation dive in 1996. We compiled details from these dives into a central, accessible format for rapid, retrospective study of DCS in this species. The database includes the significant animal characteristics, individual dive profiles, physiologic measurements, and observed clinical outcome for each of the animal dives. This effort parallels a similar compilation of human data at NMRI for mathematical modeling efforts to predict DCS outcomes. Eventually, we plan to use these databases in interspecies scaling efforts (15).

## **METHODS**

Data were collected and recorded for each study while the dive was performed, and were maintained in both handwritten form and on computer spreadsheet files. Throughout the three

years of data collection, many different formats for data recording were used in the computerized database. All of the data were reviewed and compiled into a single uniform format using Borland® QUATTRO PRO spreadsheet software. The new format was developed to assign observational fields for all pertinent outcome measures and subject characteristics. All fields and database entry cells have been annotated with data directly from the handwritten forms, from previously generated computer-based entries, or recorded/listed as not observed, when appropriate. All files were reviewed specifically to prevent duplication and scrutinized for entry errors.

## **DISCUSSION**

The information collected, recorded, and maintained varies with each study; therefore, the database provides limited descriptive information. Tables 1 and 2 summarize the manifestations by dive type. The ultimate value of an animal model is determined by its applicability to predicting human outcome. This determination can only be achieved through a clear understanding of the dose-response for DCS, the application of appropriate mathematical models of expected outcomes, and ultimately by developing a scaleable relationship between the compared species. This corpus of information serves as an archived starting point for such efforts.

06-Dec-96	671	(60.0)POOR TREADMILL, SQUEALING, JUMPING, REFUSED TO STAND AFTER 2.0 MPH
06-Dec-96	674	(1.83)MILD UNSTEADY GAIT; (5.0)HEAD SHAKING; TRANSIENT ATAXIA

## **APPENDIX 4: Graphic and Real-Time Descriptions of the Dive Programs**

### **A. Graphic Representation Key**

Solid line represents air

Dashed line represents 20% oxygen in helium

### **B. Real-time Record Key**

#### **Top Line**

1st number - depth in feet of seawater

2nd number - bottom time in minutes

3rd number - ascent time in minutes

#### **Second Line**

1st number - initial breathing gas (1.0 = air)

2nd number - number of animals that made the dive\*

3rd number - indicates outcome (0 = no outcome; 1 = DCS)\*

\*As the profiles shown in this appendix serve only to illustrate the actual dive profile, the number of animals shown is always 1, and the outcome shown is always 0.

#### **Lines 3 to end**

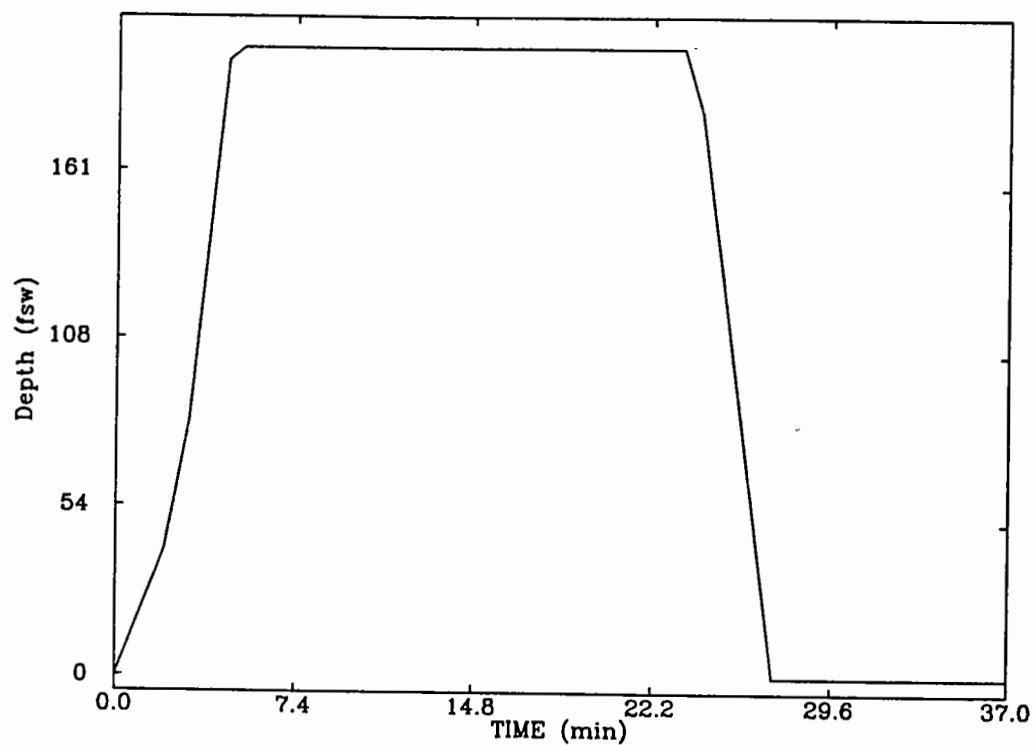

Column 1: time in minutes

Column 2: depth in feet of seawater

Column 3: breathing gas (1.0 = air; 4.2 = 20%O<sub>2</sub> in He)

Column 4: Time elapsed to complete gas switching in minutes
